The electronic structure of URu$_2$Si$_2$ in the paramagnetic phase was studied by photoelectron spectroscopy. The comparison of the valence-band and core-level spectra of URu$_2$Si$_2$ with those of itinerant U$_5$f compound UB$_2$ and localized U$_5$f compound UPd$_3$ suggests that the U$_5$f electrons in URu$_2$Si$_2$ have essentially itinerant character, but there also exists an electron correlation effect. Comparison of angle-resolved photoelectron spectroscopy (ARPES) spectra of URu$_2$Si$_2$ and ThRu$_2$Si$_2$ revealed that U$_5$f electrons form dispersive bands in the vicinity of $E_F$, suggesting that the U$_5$f states have itinerant character in URu$_2$Si$_2$. This is in contrast to the relationship between the ARPES spectra of CeRu$_2$Si$_2$ and LaRu$_2$Si$_2$ where Ce$_4$f electrons are nearly localized in CeRu$_2$Si$_2$.

Keywords: URu$_2$Si$_2$; photoelectron spectroscopy

1. Introduction

Uranium compounds exhibit a rich variety of physical properties. In particular, the coexistence of superconductivity and magnetic ordering is one of the most significant properties among these compounds [1]. Among them, URu$_2$Si$_2$ attracts much attention due to its enigmatic hidden order transition at $T_{HO}=17.5$ K [2]. Although there are a number of theoretical and experimental studies on this compound, its order parameter has not been identified for more than thirty years [3,4]. Meanwhile, photoelectron spectroscopy is a very powerful experimental technique to reveal the electronic structure of materials. In particular, angle-resolved photoelectron spectroscopy (ARPES) has been used to reveal the band structure and Fermi surface of strongly correlated materials. Numbers of photoelectron spectroscopy studies have been also performed for URu$_2$Si$_2$ to clarify its electronic structure. On the other hand, the nature of U$_5$f states in URu$_2$Si$_2$ even in the paramagnetic phase has been still controversial issue [5,6].

In the present paper, the electronic structure of URu$_2$Si$_2$ in the paramagnetic phase is studied by angle-integrated photoelectron spectroscopy (AIPES) valence-band and core-level studies. The results are compared with the AIPES spectra of typical itinerant UB$_2$ and localized compounds UPd$_3$. Furthermore, angle-resolved photoelectron spectroscopy (ARPES) was also applied for URu$_2$Si$_2$ and its non-f analogue ThRu$_2$Si$_2$ [7,8]. The results are compared with the ARPES spectra of their 4f analogs CeRu$_2$Si$_2$ and LaRu$_2$Si$_2$ [9].

2. Experimental procedures

Photoemission experiments were performed at the soft X-ray beamline BL23SU of SPring-8 [10,11]. The overall energy resolution in angle-integrated photoemission (AIPES) experiments at $h\nu = 800$ eV was about 140 meV, and that in ARPES experiments at $h\nu = 735 - 760$ eV was 100 - 140 meV, depending on the photon energies. Clean sample surfaces were obtained by cleaving the single crystal samples in situ with the surface perpendicular to the $c$ axis under ultra-high vacuum (UHV) condition. The vacuum during the course of measurements was typically $<3 \times 10^{-8}$ Pa, and the sample surfaces were stable for the duration of measurements (1-2 days) since no significant changes had been observed in ARPES spectra during the periods. The positions of ARPES cuts were determined by assuming a free-electron final state with an inner potential of $V_0 = 12$ eV by taking into account the momentum of incident photon [12].

3. Results and discussion

First, we show the AIPES spectra of URu$_2$Si$_2$ in the paramagnetic phases. Figure 1 summarizes the AIPES spectra of URu$_2$Si$_2$ measured at $h\nu = 800$ eV. The sample temperature was 20 K, and the sample was in the paramagnetic phase. Figure 1 (a) shows the AIPES spectrum of URu$_2$Si$_2$ measured in a wide energy range. There are several peaks in the spectrum, and they are assigned to the core-level spectra of uranium, ruthenium, and silicon. The signal from valence band is much weaker than those from the core-levels, and it cannot be recognized clearly in this spectrum. Figure 1 (b) shows the Ru 3$d$ core-level spectrum of URu$_2$Si$_2$. The spectrum exhibits the spin-orbit splitting, and each peak has a relatively simple peak structure. Figure 1 (c) shows the U 4$f$ core-level spectrum of URu$_2$Si$_2$. The spectrum exhibits a spin orbit splitting corresponding to U 4$f_{7/2}$ and U 4$f_{5/2}$ components, but each of them has rather complicated structures. The main line has a long tail towards the higher binding energies, and the satellite structure is observed at about 7 eV higher binding energies from the main line. This complicated structure of the U 4$f$ core-level spectrum suggests that the U 5$f$ states in URu$_2$Si$_2$ are not in simple itinerant or localized states.

In Figure 2, we show the valence band and core-level spectra of URu$_2$Si$_2$ together with those of typical itinerant compound UB$_2$ and localized compound UPd$_3$. Figure 2 (a) shows the comparison of their valence-band spectra. There is a sharp peak structure in the valence band spectrum of UB$_2$, which is the contribution from the itinerant U 5$f$ state. The spectrum of URu$_2$Si$_2$ also has similar sharp peak structure at $E_F$, suggesting that U 5$f$ states in URu$_2$Si$_2$ essentially have an itinerant character. On the other hand, there is no such peak structure in the valence-band spectrum of UPd$_3$, and the U 5$f$ states are located at around $E_F$ 0.8 eV. This is consistent with the localized U 5$f$ states in UPd$_3$. Figure 2 (b) shows the comparison of their U 4$f_{7/2}$ core-level spectra. The U 4$f$ core-level spectra exhibit a wide variety of structures. The core-level spectrum of UB$_2$ has a very simple peak structure, and its shape is very close to the core-level spectrum of simple metals, suggesting that the electron correlation effect is very weak in UB$_2$. On the other hand, the core-level spectrum of UPd$_3$ has much complicated structure. The main line of UPd$_3$ is located on the higher binding energy side of UB$_2$ by about 1.6 eV. Generally, the position of the core-level spectra is highly sensitive to the valence state. The main peak position of URu$_2$Si$_2$ is identical to that of UB$_2$, suggesting that the valence state of uranium atoms in URu$_2$Si$_2$ is close to 3 as in the case of UB$_2$. This is consistent with the result of recent U L$_{III}$ resonant X-ray emission spectroscopy study of URu$_2$Si$_2$ by Booth et al [15]. On the other hand, there exists the satellite structure in the core-level spectra of URu$_2$Si$_2$ and UPd$_3$. This satellite structure has been observed in various metallic compounds [16] and oxides [17], and considered as the influence of electron correlation effects [18]. The finite satellite intensity in URu$_2$Si$_2$ suggests that there exist the electron correlation effect in URu$_2$Si$_2$. Therefore, the U 5$f$ state in URu$_2$Si$_2$ has essentially itinerant

(a) ARPES spectra of ThRu$_2$Si$_2$ measured at $h\nu = 735$ eV. (b) ARPES spectra of URu$_2$Si$_2$ measured at $h\nu = 760$ eV. (c) ARPES spectra of LaRu$_2$Si$_2$ measured at $h\nu = 152$ eV. (d) ARPES spectra of CeRu$_2$Si$_2$ measured at $h\nu = 154$ eV.

The data of LaRu$_2$Si$_2$ and CeRu$_2$Si$_2$ were after [9]. Reprinted from Denlinger et al [9]. Copyright 2001, with permission from Elsevier.

character, but there also exists an electron correlation effect.

Figure 3 shows a comparison of ARPES spectra of ThRu$_2$Si$_2$ [8], URu$_2$Si$_2$ [7], LaRu$_2$Si$_2$, and CeRu$_2$Si$_2$ [9]. The photon energies used were $h\nu = 735$ eV for ThRu$_2$Si$_2$, 760 eV for URu$_2$Si$_2$, 152 eV for LaRu$_2$Si$_2$, and 154 eV for CeRu$_2$Si$_2$. The data of LaRu$_2$Si$_2$ and CeRu$_2$Si$_2$ were taken from Ref. [9]. The sample temperatures were 20 K for the cases of ThRu$_2$Si$_2$ and URu$_2$Si$_2$, 152 eV for LaRu$_2$Si$_2$, and $< 150$ K for the cases of LaRu$_2$Si$_2$ and CeRu$_2$Si$_2$. Both sets of data correspond to the scan along the $Z - \Gamma - X - \Gamma$ high-symmetry line though the incident photon energies are considerably different between the cases of (U, Th)Ru$_2$Si$_2$ and (Ce, La)Ru$_2$Si$_2$. There are some similarities between the ARPES spectra of (U, Th)Ru$_2$Si$_2$ and (Ce, La)Ru$_2$Si$_2$. In particular, the parabolic dispersions with enhanced intensities and their apex at the $\Gamma$ point are very similar. On the other hand, their appearances are somewhat different due to the different matrix element effects in different photon energies. First, we focus on the comparison between the ARPES spectra of ThRu$_2$Si$_2$ and URu$_2$Si$_2$. They have essentially similar structures, but their details are considerably different. In particular, the features in the vicinity of $E_F$ are very different between these two compounds. For example, there are dispersive bands in the vicinity of $E_F$ along the $Z \Gamma$ line in the ARPES spectra of URu$_2$Si$_2$, but there are no corresponding bands in the ARPES spectra of ThRu$_2$Si$_2$. These dispersive features in the vicinity of $E_F$ are contributions from U 5$f$ states, suggesting that U 5$f$ have an itinerant nature in URu$_2$Si$_2$. On the other hand, the ARPES spectra of LaRu$_2$Si$_2$ and CeRu$_2$Si$_2$ are very similar each other, which is in contrast with the case of (U, Th)Ru$_2$Si$_2$. The difference between the ARPES spectra of CeRu$_2$Si$_2$ and LaRu$_2$Si$_2$ is essentially limited only in the vicinity of $E_F$, where the at peak was observed in some part of the Brillouin zone. They correspond to the contribution from itinerant component of Ce 4$f$ state, but their band dispersions are extremely narrow, suggesting that the Ce 4$f$ states are nearly localized in CeRu$_2$Si$_2$. An interesting point to note is that the Ru 4$d$ states are almost identical between the ARPES spectra of LaRu$_2$Si$_2$ and CeRu$_2$Si$_2$, while they are considerably different between the ARPES spectra of ThRu$_2$Si$_2$ and URu$_2$Si$_2$. This means that U 5$f$ states are considerably hybridized with the Ru 4$d$ states in URu$_2$Si$_2$ while Ce 4$f$ states are almost localized in CeRu$_2$Si$_2$.

4. Conclusion

We have studied the valence-band and core-level spectra of URu$_2$Si$_2$. The comparison of the core-level spectrum of URu$_2$Si$_2$ with those of UB$_2$ and UPd$_3$ suggests that the number of U 5$f$ occupation number
in URu$_2$Si$_2$ is close to 3 as in the case of UB$_2$. The comparison of ARPES spectra between (U, Th)Ru$_2$Si$_2$ and (Ce, La)Ru$_2$Si$_2$ indicated that U 5f states are strongly hybridized with Ru 4d states whereas Ce 4f states in CeRu$_2$Si$_2$ are nearly localized in CeRu$_2$Si$_2$. According to these results, the U 5f states in URu$_2$Si$_2$ have strong itinerant character, but the finite contribution from the electron correlation effect exists.
